

The Domain Model

Unlike other engineers, software engineers work on different areas, with various needs and business rules.

For example; they develop software for airline companies, for banks, for embedded systems like car engines.

Therefore, it is not sufficient to know about *software domain*, a software engineer also needs to know about the *problem domain*.

A domain model illustrates concepts in a problem domain (real-world).

UML class diagrams are used to present domain models.

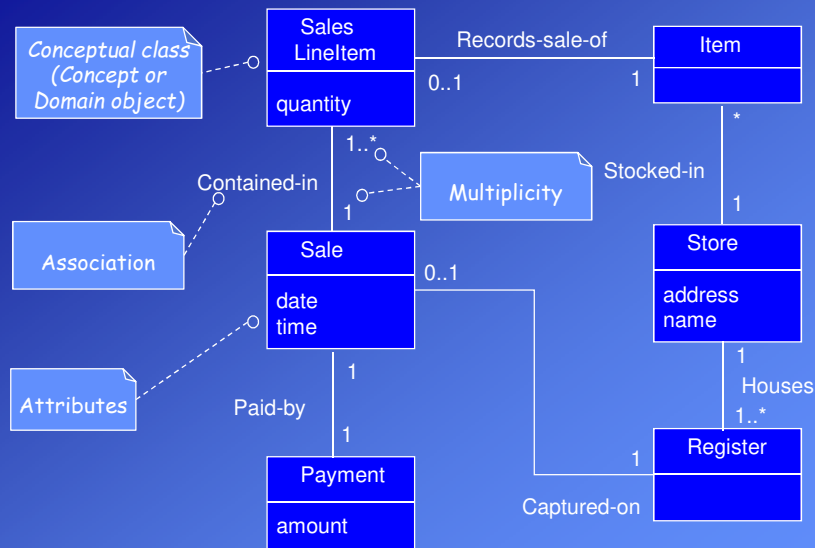

It may show three items:

- domain objects or conceptual classes
- associations between conceptual classes
- attributes of conceptual classes

Benefits of the domain model:

1. It helps to understand the system.
2. It acts as a source to define software classes in design level.

Example: A Partial Domain Model

Object Oriented Modeling and Design

A domain model shows real-situation conceptual classes, not software classes.

Real-world concept:
OK for domain model

Software artifacts are not a part of domain model.

Avoid. Software artifact. May be included in design model.

Avoid. Software classes.
Responsibilities will be assigned in design step.

3.3

Object Oriented Modeling and Design

Lower representational gap between real-world and software system

Names and responsibilities of software classes in design level are inspired from conceptual classes in the domain model.

Domain (analysis) model and software (design) model will not be the same but similar.

3.4

Object Oriented Modeling and Design

How to Create the Domain Model?

1. Find the conceptual classes.
2. Add associations and attributes.
3. Draw them as classes in a UML class diagram.

How to Find Conceptual Classes?

Three strategies to find conceptual classes:

1. Reuse or modify existing models.
If there is an existing model from a previous project, it can be modified.
There are also published domain models for many common domains, such as inventory, finance, health, and so forth.
2. Use a category list.
You can define conceptual classes in your application domain by using the list that contains many common categories.
3. Identify noun phrases in the use cases.

3.5

Object Oriented Modeling and Design

Finding Conceptual Classes with Noun Phrase Identification

Identify the nouns and noun phrases in textual descriptions of a domain (use cases), and consider them as candidate conceptual classes or attributes.

Main Success Scenario (or Basic Flow):

1. Customer arrives at a POS checkout with goods and/or services to purchase.
2. Cashier starts a new sale.
3. Cashier enters item identifier.
4. System records sale line item and presents item description, price, and running total. Price calculated from a set of price rules.
Cashier repeats steps 3-4 until indicates done.
5. System presents total with taxes calculated.
6. Cashier tells Customer the total, and asks for payment.
7. Customer pays and System handles payment.
8. System logs completed sale and sends sale and payment information to the external Accounting system (for accounting and commissions) and Inventory system (to update inventory).
9. System presents receipt.
10. Customer leaves with receipt and goods (if any).

Extensions:

- 7a. Paying by cash:
 1. Cashier enters the cash amount tendered.
 2. System presents the balance due.

3.6

Eliminating unnecessary noun phrase

All noun phrases in use cases do not represent conceptual classes.

Following noun phrases should be eliminated:

1. Different noun phrases may represent the same conceptual class.
For example, customer and user are redundant . Use "customer" because it is more descriptive.
2. Some noun phrases may refer to conceptual classes that are ignored in this iteration (for example, "accounting" and "commissions").
3. Some noun phrases may refer to attributes. Attributes should be basic data types such as, number, text.

This method can be used in combination with the "Conceptual Class Category List" technique.

The Mapmaker Approach

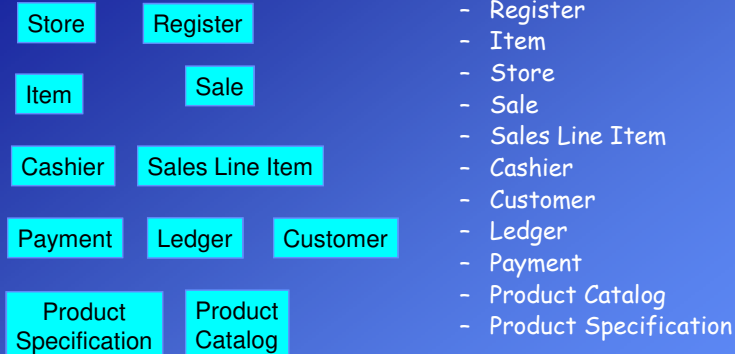

A domain model is a kind of map of concepts or things in an application domain.

Make a domain model in the spirit of how a cartographer or mapmaker works:

- **Use the existing names** in the territory.
Mapmakers do not change the names of cities on a map.
Use the vocabulary of the domain when naming conceptual classes and attributes.
- **Exclude irrelevant features.**
For example, in a physical map, borders of cities are not shown.
Do not put classes or attributes on the model if they do not have any obvious noteworthy role. For example; keyboard, the age of cashier.
- **Do not add things that are not there.**
A mapmaker does not show things that are not there, such as a mountain that does not exist.
Similarly, the domain model should exclude things *not* in the problem domain under consideration. For example; the owner of the store.

Object Oriented Modeling and Design

Example: Conceptual classes of NextGen POS system

There is no such thing as a "correct" list.
However, by following the identification strategies, different modelers will produce similar lists.

3.9

Object Oriented Modeling and Design

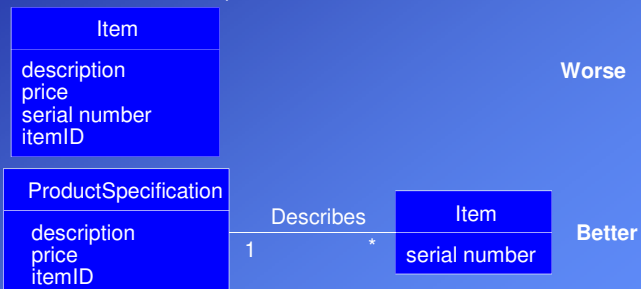

Need for description (specification) classes

Assume that information about physical items in a store are written on these items; such as serial number and price.

It seems logical, because these data are attributes of these items.

But when all items are sold out some data may be lost.

In such systems, it is necessary to keep these data in separate description classes.

Add a description class (for example, ProductSpecification) when:

- We need the description about an item, even the examples of this item currently does not exist in the system.
- Deleting instances of things they describe (for example, Item) results in a loss of information that needs to be maintained.
- It reduces redundant or duplicated information.

3.10

Associations

An **association** is a relationship between classes that indicates some meaningful connection .

- Because the domain model displays conceptual classes in real-world, associations also refer to real situations.
- Associations are not function calls between software classes.
- Associations in domain model are mostly bidirectional.

Example: Register records current Sale. (From left to right)

Current Sale is recorded by Register. (From right to left)

Multiplicity

Multiplicity defines how many instances (objects) of a class A can be associated at the same time (at a particular moment) with one instance of a class B.

Left to right: One student takes at least one or more courses.

Right to left: One course is taken at least by five or more students.

Multiplicity numbers are obtained from the requirements of the user.

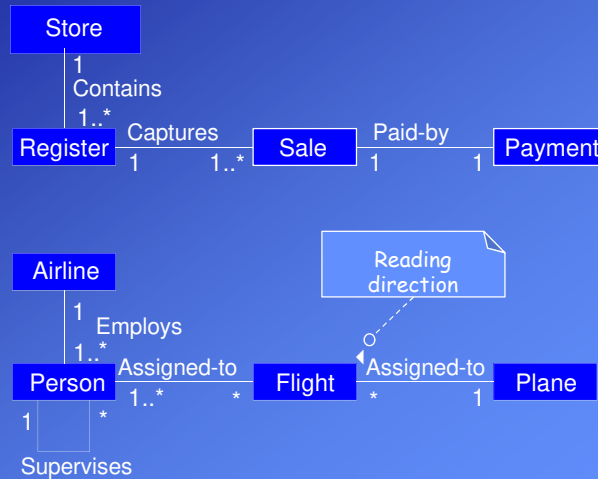

Object Oriented Modeling and Design

Finding Associations

Associations can be defined

1. by using the common associations list
2. by using verbs in use cases

Examples:

3.14

Object Oriented Modeling and Design

Attributes

Identify attributes of conceptual classes (real-world attributes not software data).

Include attributes that the requirements (for example, use cases) suggest or imply a need to remember information.

For example; register number of a student, date and time of a sale.

Attribute types should be "primitive" data types, such as numbers, characters, and booleans.

The type of an attribute should not normally be a complex domain concept.

If a concept has its own properties and behavior, then its is not a simple attribute, it is a separate conceptual class.

3.16

Operation Contracts

Use cases and domain models are usually sufficient to understand requirements of the user and the expected features of the system under discussion.

Now it is possible to start with design.

However, sometimes a more detailed or precise description of system behavior is necessary.

In that case, an operation contract is written for each **complex system operation** (statement) in the use cases to describe its details.

Examples for system operations: "Make new sale", "Enter Item ID", "End sale".

An **operation contract** describes changes in the state of objects in the domain model when the related operation has finished.

In other words, it describes what happened to the objects in the system during the execution of the related operation.

Remember, we are still in the real-world (application domain); we are not talking about software objects or attributes.

Operation contracts help us to find responsibilities of the system.

<http://www.faculty.itu.edu.tr/buzluca>
<http://www.buzluca.info>

©2012-2017 Dr. Feza BUZLUCA

3.17

Format of an operation contract

Contract number and name

Operation: Name and parameters (signature)

Reference: The related use case

Preconditions: What must be true to run this operation.

Postconditions: Changes in the state of objects in the domain model.

The **postconditions** describe changes in the state of objects in the domain model when the related operation has finished.

Postconditions are divided into three categories:

1. Instance (object) creation and deletion.
2. Attribute change of value.
3. Associations (links, connections) formed and broken.

Remember, we are looking for the answer to "what".

How these operations are performed is an issue that we deal with in the design step.

Postconditions give us the **responsibilities** that we must assign to the objects in design.

©2012-2017 Dr. Feza BUZLUCA

3.19

Object Oriented Modeling and Design

How to write postconditions?

Postconditions are not actions to be performed during the operation; rather, they are observations about the domain model objects that are true when the operation has finished.

What happened to the objects in the system (real-world) after the operation?

We are still interested in **what** happened, not **how** it is performed.

How this contracts are realized is the issue of the design level.

Express postconditions in the **past tense** to emphasize they are observations about state changes.

Analogy: The Stage of a theater (Taken from Larman)

The system and its objects are presented on a theatre stage.

1. Before the operation, take a picture of the stage.
2. Close the curtains on the stage, and apply the system operation (background noise of clanging, screams, and screeches...).
3. Open the curtains and take a second picture.
4. Compare the before and after pictures, and express as postconditions the changes in the state of the stage (A SalesLineItem was created...).

Now we know the changes, but not how (by whom) they are made.

3.20

Object Oriented Modeling and Design

Example: enterItem

The statement in the use case "Cashier enters item identifier." can be a complicated operation. Therefore we write a contract for this operation.

All objects (for example sli), mentioned in contracts are related to the domain model (3.16). We are not writing the program.

Contract CO2: enterItem**Operation:**

enterItem(itemID: ItemID, quantity: integer)

Reference: Use Cases: Process Sale

PreCond.: There is a sale underway

PostConditions:

- A SalesLineItem instance sli was created (instance creation)
- sli was associated with the current Sale (association formed)
- sli.quantity became quantity (attribute modification)
- sli was associated with a Product Spec. based on itemID match (association formed)

<http://www.faculty.itu.edu.tr/buzluca>
<http://www.buzluca.info>

©2012-2017 Dr. Feza BUZLUCA

3.21

Object Oriented Modeling and Design

Example: endSale

Assume that in NextGen POS system completed sales are not deleted, they are only marked as "completed" and logged in the system.

Contract CO3: endSale**Operation:**

endSale()

Cross References:

Use Cases: Process Sale

PreConditions:

There is a sale underway

PostConditions:

- Sale.isComplete became true (attribute modification)

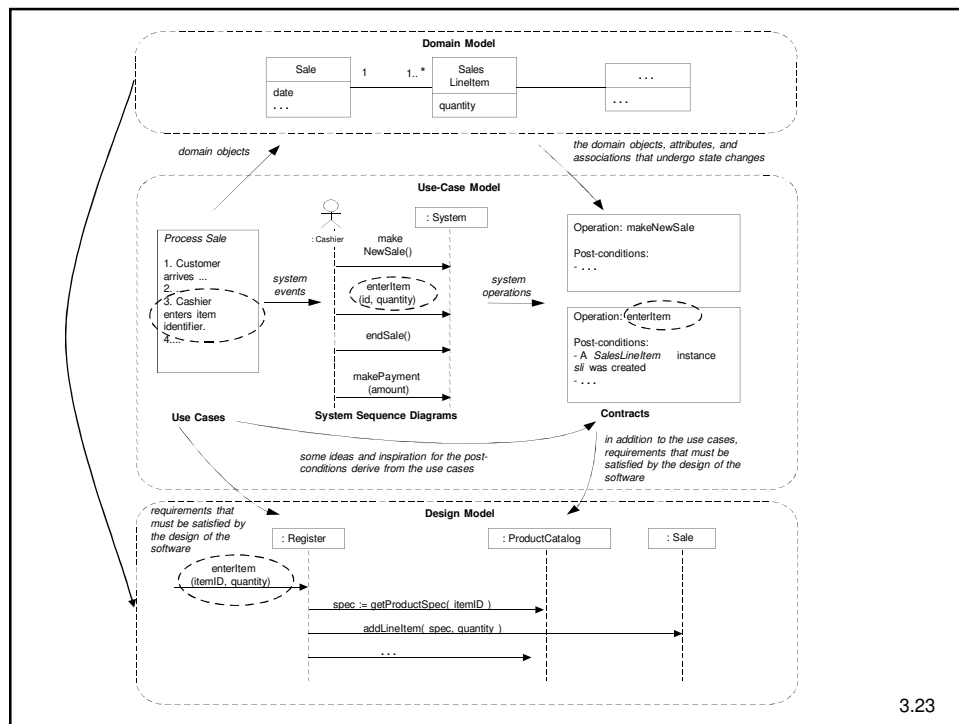

This attribute was not in the domain model.
We discovered it during writing the contract.
